Use of tetracycline stains to estimate phosphorus availability in contaminated soils. Accurate and reproducible measures of soil phosphorus (P) availability are of importance in conservation planning and management. The popular tetracycline (TC) method of assessing P availability uses an in situ dose of the herbicide, tetracycline. However, estimates of P availability are inconsistent across studies. This study uses a laboratory incubation technique to simulate the typical dosing and incubation conditions of the TC method. The results of the laboratory experiment were compared to three commonly used soil assessment methods. The results showed that, on average, the TC method overestimated soil P availability by a factor of four and would miss almost half of the available P in the sample. The nitrate-N test underestimated P availability by three- to fourfold. The P concentration method, the bromide extraction method, and the nitrate-N test produced similar estimates of P availability. The results show that the TC method should be interpreted cautiously as it does not appear to accurately estimate soil P availability. Overall, the N methods were better indicators of soil P availability than the TC method.
